Add WeChat powcoder

What kind of games?

- **Abstraction:** To describe a game we must capture every relevant aspect of the game. Such as:
 - Chess
 - Tic-tac-toe
 - ...
- **Accessible environments:** Such games are characterized by perfect information
- **Search:** game-playing then consists of a search through possible game positions
- **Unpredictable opponent:** introduces **uncertainty** thus game-playing must deal with **contingency problems**

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

Searching for the next move

- **Complexity:** many games have a huge search space

- **Chess:** $b = 35, m=100 \Rightarrow \text{nodes} = 35^{100}$

if each node takes about 1 ns to explore
then each move will take about 10⁵⁰ millennia
to calculate.

- **Resource (e.g., time, memory) limit:** optimal solution not feasible/possible, thus must approximate

1. **Pruning:** makes the search more efficient by discarding portions of the search tree that cannot improve quality result.
2. **Evaluation functions:** heuristics to evaluate utility of a state without exhaustive search.

Two-player games

- A game formulated as a search problem:
 - Initial state: ?
 - Operators: ?
 - Terminal state: ?
 - Utility function: ?

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

Two-player games

- A game formulated as a search problem:

- Initial state: board position and turn
- Operators: definition of legal moves
- Terminal state: conditions for when game is over
- Utility function: a numeric value that describes the outcome of the game. E.g., -1, 0, 1 for loss, draw, win.
(AKA **payoff function**)

Game vs. search problem

“Unpredictable” opponent \Rightarrow solution is a contingency plan

Time limits \Rightarrow unlikely to find goal, must approximate

Plan of attack: <https://powcoder.com>

- algorithm for perfect play (Von Neumann, 1944)
- finite horizon, approximate evaluation (Zuse, 1945; Shannon, 1950; Samuel, 1952–57)
- pruning to reduce costs (McCarthy, 1956)

Example: Tic-Tac-Toe

Type of games

Assignment Project Exam Help

The minimax algorithm

- Perfect play for deterministic environments with perfect information
- **Basic idea:** choose move with highest minimax value
= best achievable payoff against best play
- **Algorithm:**
 1. Generate game tree completely
 2. Determine utility of each terminal state
 3. Propagate the utility values upward in the tree by applying MIN and MAX operators on the nodes in the current level
 4. At the root node use minimax decision to select the move with the max (of the min) utility value
- Steps 2 and 3 in the algorithm assume that the opponent will play perfectly.

- Minimize opponent's chance
- Maximize your chance

Minimax

- Minimize opponent's chance
- Maximize your chance

Minimax

- Minimize opponent's chance
- Maximize your chance

Minimax

- Minimize opponent's chance
- Maximize your chance

minimax = maximum of the minimum

Minimax: Recursive implementation

```
function MINIMAX-DECISION(state) returns an action  
  return  $\arg \max_{a \in \text{ACTIONS}(s)} \text{MIN-VALUE}(\text{RESULT}(state, a))$ 
```

```
function MAX-VALUE(state) returns a utility value  
  if TERMINAL-TEST(state) then return UTILITY(state)  
   $v \leftarrow -\infty$   
  for each  $a$  in ACTIONS(state) do  
     $v \leftarrow \text{MAX}(v, \text{MIN-VALUE}(\text{RESULT}(s, a)))$   
  return  $v$ 
```

```
function MIN-VALUE(state) returns a utility value  
  if TERMINAL-TEST(state) then return UTILITY(state)  
   $v \leftarrow \infty$   
  for each  $a$  in ACTIONS(state) do  
     $v \leftarrow \text{MIN}(v, \text{MAX-VALUE}(\text{RESULT}(s, a)))$   
  return  $v$ 
```

Complete: ?

Optimal: ?

Time complexity: ?

Space complexity: ?

Minimax: Recursive implementation

  return  $v$ 
```

Complete: Yes, for finite state-space

Optimal: Yes

Time complexity: $O(b^m)$

Space complexity: $O(bm)$ (= DFS

Does not keep all nodes in memory.)

1. Move evaluation without complete search

- Complete search is too complex and impractical
- **Evaluation function:** evaluates value of state using **heuristics** and cuts off search

<https://powcoder.com>

- **New MINIMAX:**
 - **CUTOFF-TEST:** cutoff test to replace the termination condition (e.g., deadline, depth-limit, etc.)
 - **EVAL:** evaluation function to replace utility function (e.g., number of chess pieces taken)

Evaluation functions

- **Weighted linear evaluation function:** to combine n heuristics

$$f = w_1 f_1 + w_2 f_2 + \dots + w_n f_n$$

E.g, w 's could be the values of pieces (1 for pawn, 3 for bishop etc.)
 f 's could be the number of type of pieces on the board

Note: exact values do not matter

Behaviour is preserved under any *monotonic* transformation of EVAL

Only the order matters:

payoff in deterministic games acts as an *ordinal utility* function

Minimax with cutoff: viable algorithm?

MINIMAXCUTOFF is identical to MINIMAXVALUE except

1. TERMINAL? is replaced by CUTOFF?
2. UTILITY is replaced by EVAL

Does it work in practice?

$$b^m = 10^6, \quad b = 35 \rightarrow m = 4$$

4-ply lookahead is a hopeless chess player!

4-ply \approx human novice

8-ply \approx typical PC, human master

12-ply \approx Deep Blue, Kasparov

2. α - β pruning: search cutoff

- **Pruning:** eliminating a branch of the search tree from consideration without exhaustive examination of each node

Assignment Project Exam Help

- **α - β pruning:** the basic idea is to prune portions of the search tree that cannot improve the utility value of the max or min node, by just considering the values of nodes seen so far.

<https://powcoder.com>

Add WeChat powcoder

- Does it work? Yes, it roughly cuts the branching factor from b to \sqrt{b} resulting in double as far look-ahead than pure minimax

Demo

Enter the game tree structure: (hint: Insert the game tree structure composed by a list with the number of child nodes for each internal node, ordered by level and left to right)

Enter the game tree terminal values: (hint: Insert the utility values for the game tree terminal/leaf nodes ordered left to right)

Messages:

α - β pruning: example

Interactive demo:

<https://www.yosenspace.com/posts/computer-science-game-trees.html>

α - β pruning: general principle

Properties of α - β

Pruning *does not* affect final result

Good move ordering improves effectiveness of pruning

With “perfect ordering”: time complexity = $O(b^{m/2})$

⇒ *doubles* depth of search

⇒ can easily reach depth 8 and play good chess

A simple example of the value of reasoning about which computations are relevant (a form of *metareasoning*)

function ALPHA-BETA-SEARCH($state$) **returns** an action
 $v \leftarrow \text{MAX-VALUE}(state, -\infty, +\infty)$
return the *action* in $\text{ACTIONS}(state)$ with value v

function MAX-VALUE($state, \alpha, \beta$) **returns** a utility value
if $\text{TERMINAL-TEST}(state)$ **then return** $\text{UTILITY}(state)$
 $v \leftarrow -\infty$
for each a **in** $\text{ACTIONS}(state)$ **do**
 $v \leftarrow \text{MAX}(v, \text{MIN-VALUE}(\text{RESULT}(s, a), \alpha, \beta))$
if $v \geq \beta$ **then return** v
 $\alpha \leftarrow \text{MAX}(\alpha, v)$
return v

function MIN-VALUE($state, \alpha, \beta$) **returns** a utility value
if $\text{TERMINAL-TEST}(state)$ **then return** $\text{UTILITY}(state)$
 $v \leftarrow +\infty$
for each a **in** $\text{ACTIONS}(state)$ **do**
 $v \leftarrow \text{MIN}(v, \text{MAX-VALUE}(\text{RESULT}(s, a), \alpha, \beta))$
if $v \leq \alpha$ **then return** v
 $\beta \leftarrow \text{MIN}(\beta, v)$
return v

Add WeChat powcoder

More on the α - β algorithm

- Same basic idea as minimax, but prune (cut away) branches of the tree that we know will not contain the solution.

Assignment Project Exam Help

<https://powcoder.com>

- We know a branch will not contain a solution once we know a better outcome has already been discovered in a previously explored branch.

Remember: Minimax: Recursive implementation

```
function MINIMAX-DECISION(state) returns an action  
  return  $\arg \max_{a \in \text{ACTIONS}(s)} \text{MIN-VALUE}(\text{RESULT}(state, a))$ 
```

```
function MAX-VALUE(state) returns a utility value  
  if TERMINAL-TEST(state) then return UTILITY(state)  
   $v \leftarrow -\infty$   
  for each  $a$  in ACTIONS(state) do  
     $v \leftarrow \text{MAX}(v, \text{MIN-VALUE}(\text{RESULT}(s, a)))$   
  return  $v$ 
```

```
function MIN-VALUE(state) returns a utility value  
  if TERMINAL-TEST(state) then return UTILITY(state)  
   $v \leftarrow \infty$   
  for each  $a$  in ACTIONS(state) do  
     $v \leftarrow \text{MIN}(v, \text{MAX-VALUE}(\text{RESULT}(s, a)))$   
  return  $v$ 
```

Complete: Yes, for finite state-space

Optimal: Yes

Time complexity: $O(b^m)$

Space complexity: $O(bm)$ (= DFS

Does not keep all nodes in memory.)

function ALPHA-BETA-SEARCH($state$) **returns** an action
 $v \leftarrow \text{MAX-VALUE}(state, -\infty, +\infty)$
return the *action* in $\text{ACTIONS}(state)$ with value v

function MAX-VALUE($state, \alpha, \beta$) **returns** a utility value
if $\text{TERMINAL-TEST}(state)$ **then return** $\text{UTILITY}(state)$
 $v \leftarrow -\infty$
for each a **in** $\text{ACTIONS}(state)$ **do**
 $v \leftarrow \text{MAX}(v, \text{MIN-VALUE}(\text{RESULT}(s, a), \alpha, \beta))$
~~**if** $v \geq \beta$ **then return** v~~
 $\alpha \leftarrow \text{MAX}(\alpha, v)$
return v

function MIN-VALUE($state, \alpha, \beta$) **returns** a utility value

More on the α - β algorithm

- Same basic idea as minimax, but prune (cut away) branches of the tree that we know will not contain the solution.

Assignment Project Exam Help

- Because minimax is depth-first, let's consider nodes along a given path in the tree. Then, as we go along this path, we keep track of:

- α : Best choice so far for MAX
- β : Best choice so far for MIN

<https://powcoder.com>
Add WeChat powcoder

The α - β algorithm

function ALPHA-BETA-SEARCH($state$) **returns** an action
 $v \leftarrow \text{MAX-VALUE}(state, -\infty, +\infty)$
 return the *action* in $\text{ACTIONS}(state)$ with value v

function MAX-VALUE($state, \alpha, \beta$) **returns** a utility value
 if $\text{TERMINAL-TEST}(state)$ **then return** $\text{UTILITY}(state)$
 $v \leftarrow -\infty$
 for each a **in** $\text{ACTIONS}(state)$ **do**
 $v \leftarrow \text{MAX}(v, \text{MIN-VALUE}(\text{RESULT}(s, a), \alpha, \beta))$
 if $v \geq \beta$ **then return** v
 $\alpha \leftarrow \text{MAX}(\alpha, v)$
 return v

function MIN-VALUE($state, \alpha, \beta$) **returns** a utility value
 if $\text{TERMINAL-TEST}(state)$ **then return** $\text{UTILITY}(state)$
 $v \leftarrow +\infty$
 for each a **in** $\text{ACTIONS}(state)$ **do**
 $v \leftarrow \text{MIN}(v, \text{MAX-VALUE}(\text{RESULT}(s, a), \alpha, \beta))$
 if $v \leq \alpha$ **then return** v
 $\beta \leftarrow \text{MIN}(\beta, v)$
 return v

Note: α and β are both Local variables. At the Start of the algorithm, We initialize them to $\alpha = -\infty$ and $\beta = +\infty$

- For a given node N ,

Assignment Project Exam Help

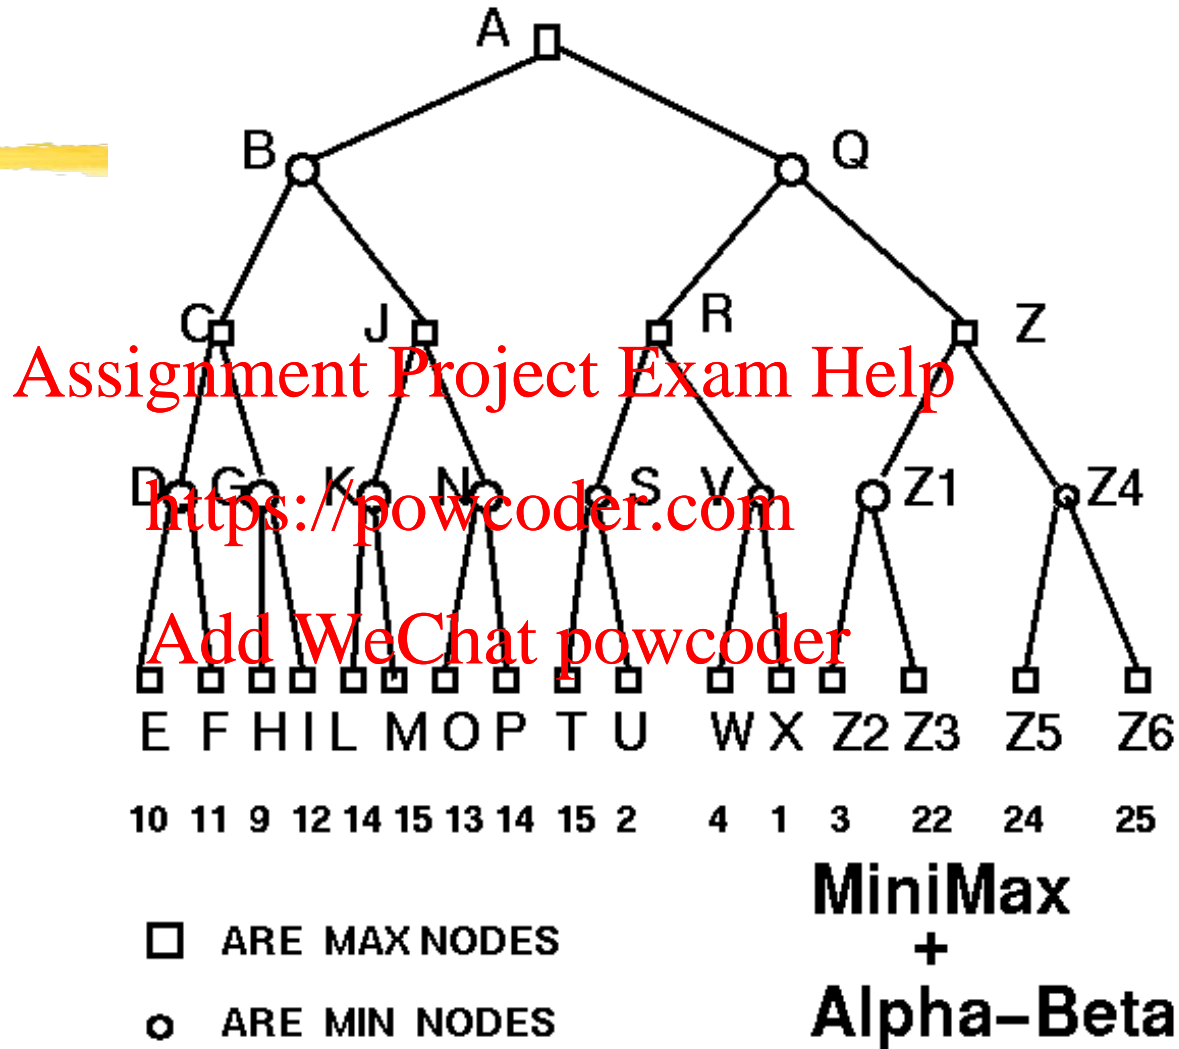

α is the value of N to MAX

β is the value of N to MIN

<https://powcoder.com>

Add WeChat powcoder

Example

α - β algorithm: slight variant (from earlier version of textbook)

Basically MINIMAX + keep track of α , β + prune

function MAX-VALUE(*state*, *game*, α , β) **returns** the minimax value of *state*

inputs: *state*, current state in game

game, game description

α , the best score for MAX along the path to *state*

β , the best score for MIN along the path to *state*

if CUTOFF-TEST(*state*) **then return** EVAL(*state*)

for each *s* **in** SUCCESSORS(*state*) **do**

$\alpha \leftarrow \text{MAX}(\alpha, \text{MIN-VALUE}(s, \text{game}, \alpha, \beta))$

if $\alpha \geq \beta$ **then return** β

end

return α

function MIN-VALUE(*state*, *game*, α , β) **returns** the minimax value of *state*

if CUTOFF-TEST(*state*) **then return** EVAL(*state*)

for each *s* **in** SUCCESSORS(*state*) **do**

$\beta \leftarrow \text{MIN}(\beta, \text{MAX-VALUE}(s, \text{game}, \alpha, \beta))$

if $\beta \leq \alpha$ **then return** α

end

return β

State-of-the-art for deterministic games

Checkers: Chinook ended 40-year-reign of human world champion Marion Tinsley in 1994. Used an endgame database defining perfect play for all positions involving 8 or fewer pieces on the board, a total of 443,748,401,247 positions.

Chess: Deep Blue defeated human world champion Gary Kasparov in a six-game match in 1997. Deep Blue searches 200 million positions per second, uses very sophisticated evaluation, and undisclosed methods for extending some lines of search up to 40 ply.

Othello: human champions refuse to compete against computers, who are too good.

Go: human champions refuse to compete against computers, who are too bad. In go, $b > 300$, so most programs use pattern knowledge bases to suggest plausible moves.

Nondeterministic games

E..g, in backgammon, the dice rolls determine the legal moves

Simplified example with coin-flipping instead of dice-rolling:

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

Algorithm for nondeterministic games

EXPECTIMINIMAX gives perfect play

Just like MINIMAX, except we must also handle chance nodes:

```
...  
if state is a chance node then  
    return average of EXPECTIMINIMAX-VALUE of SUCCESSORS(state)  
...
```

A version of α - β pruning is possible
but only if the leaf values are bounded. Why??

Remember: Minimax algorithm

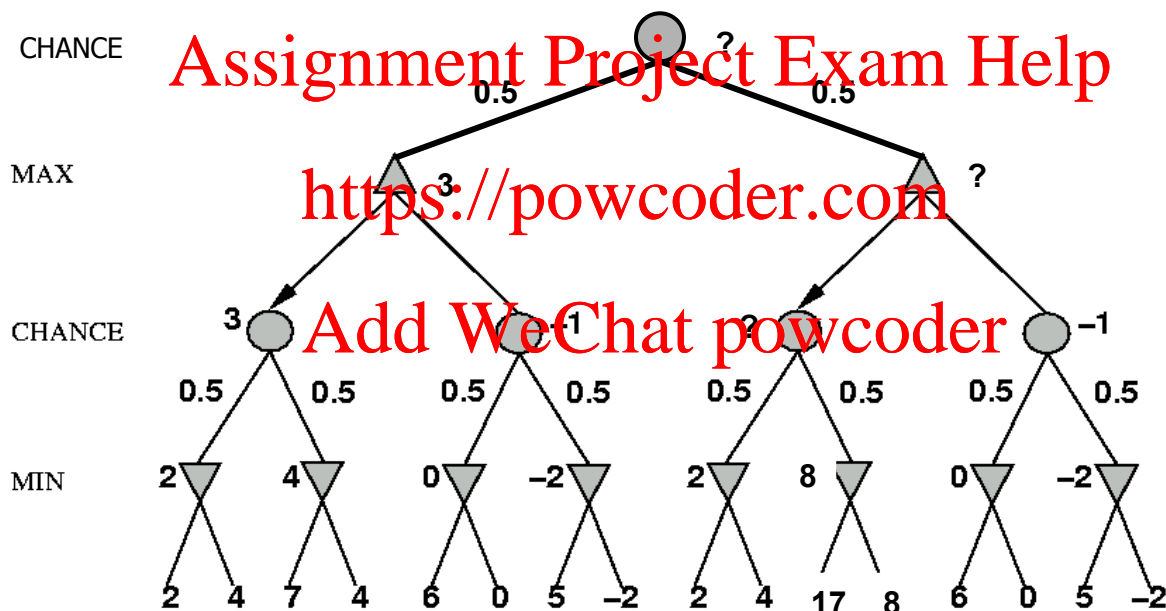

function MINIMAX-DECISION(*state*) **returns** *an action*
return $\arg \max_{a \in \text{ACTIONS}(s)} \text{MIN-VALUE}(\text{RESULT}(\text{state}, a))$

function MAX-VALUE(*state*) **returns** *a utility value*
if TERMINAL-TEST(*state*) **then return** UTILITY(*state*)
 $v \leftarrow -\infty$
for each *a* **in** ACTIONS(*state*) **do**
 $v \leftarrow \text{MAX}(v, \text{MIN-VALUE}(\text{RESULT}(s, a)))$
return *v*

function MIN-VALUE(*state*) **returns** *a utility value*
if TERMINAL-TEST(*state*) **then return** UTILITY(*state*)
 $v \leftarrow \infty$
for each *a* **in** ACTIONS(*state*) **do**
 $v \leftarrow \text{MIN}(v, \text{MAX-VALUE}(\text{RESULT}(s, a)))$
return *v*

Nondeterministic games: the element of chance

expectimax and **expectimin**, expected values over all possible outcomes

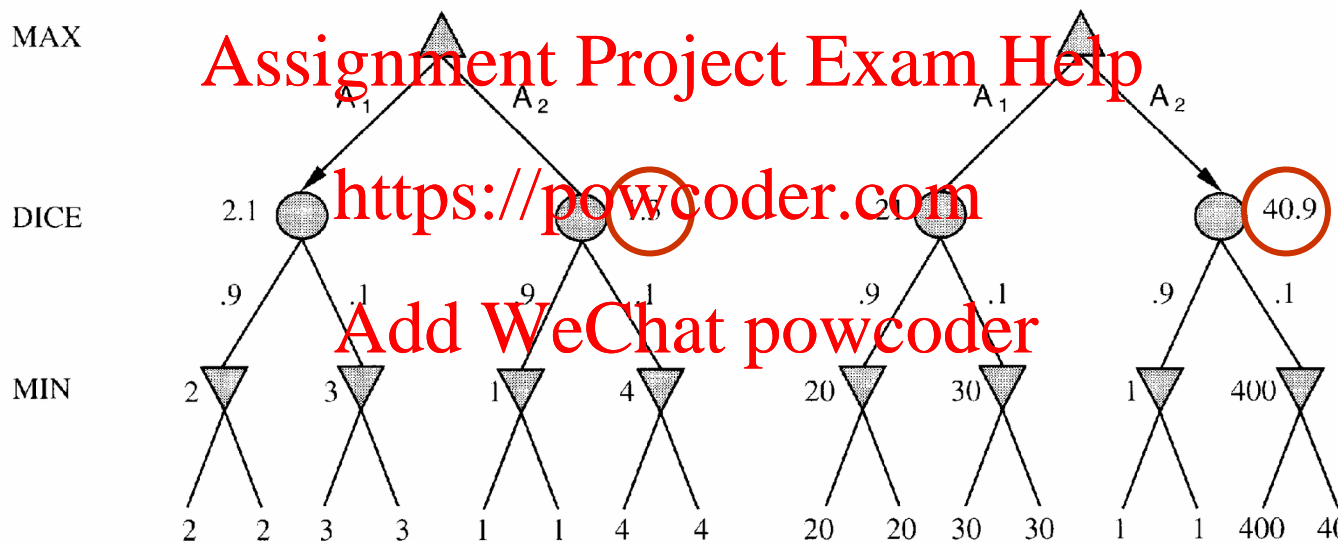

Nondeterministic games: the element of chance

Evaluation functions: Exact values DO matter

Order-preserving transformations do not necessarily behave the same!

State-of-the-art for nondeterministic games

Dice rolls increase b : 21 possible rolls with 2 dice
Backgammon ≈ 20 legal moves (can be 6,000 with 1-1 roll)

$$\text{depth } 4 = 20 \times (21 \times 20)^3 \approx 1.2 \times 10^9$$

As depth increases, probability of reaching a given node shrinks
 \Rightarrow value of lookahead is diminished

α - β pruning is much less effective

Summary

Games are fun to work on! (and dangerous)

They illustrate several important points about AI

- ◇ perfection is unattainable \Rightarrow must approximate
- ◇ good idea to think about what to think about
- ◇ uncertainty constrains the assignment of values to states

Games are to AI as grand prix racing is to automobile design

Exercise: Game Playing

Consider the following game tree in which the evaluation function values are shown below each leaf node. Assume that the root node corresponds to the maximizing player. Assume the search always visits children left-to-right.

Assignment Project Exam Help

- (a) Compute the backed-up values computed by the minimax algorithm. Show your answer by writing values at the appropriate nodes in the above tree.

- (b) Compute the backed-up values computed by the alpha-beta algorithm. What nodes will not be examined by the alpha-beta pruning algorithm?

- (c) What move should Max choose once the values have been backed-up all the way?
